

# 1 Infinite Words

**Theorem 1.1.** *Every non-empty  $\omega$ -regular language contains an ultimately periodic word.*

*Proof.* Let  $U$  be  $\omega$ -regular, so there is a regular expression  $r = \bigcup_{i=1}^n U_i \cdot V_i^\omega$  for it. Since  $U \neq \emptyset$ ,  $n$  must be larger than 0. Let  $u \in U_1$  and  $v \in V_1$  be arbitrary. Then  $uv^\omega \in U$ .  $\square$

**Theorem 1.2.** *For a Kripke structure  $\mathcal{K}$  with initial state  $s$  and  $\varphi \in \text{LTL}$ , the model checking problem  $L(\mathcal{K}, s) \subseteq L(\varphi)?$  is PSPACE-complete.*

*Proof.* **PSPACE** Compute the intersection automaton for  $L(\mathcal{K}, s) \cap L(\neg\varphi)$  and test it for emptiness.

**PSPACE-hard** Encode a poly-length Turing tape as a Kripke structure and its correct behavior in LTL.  $\square$

**Theorem 1.3** (Büchi). *The MSO theory of  $(\mathbb{N}, +1, <, 0)$  is decidable.*

*Proof.* Corresponds to S1S formula. Can be checked with NBA emptiness test.  $\square$

**Theorem 1.4.** *The FO theory of  $(\mathbb{R}, +, <, 0)$  is decidable.*

*Proof.* Encode real numbers  $x$  by triples of sets  $(X_s, X_i, X_f)$  with the number's sign ( $X_s = \emptyset$  or  $\{0\}$ ), the positive decimal digits in binary encoding, and the positive fractional digits in binary encoding. Then an FO sentence can be transformed to an equi-satisfiable MSO sentence over  $(\mathbb{N}, +1, <, 0)$ .  $\square$

**Theorem 1.5.** *Subset-construction does not suffice to determinize NBAs.*

*Proof.* Example: Let  $\mathcal{A} = (Q, \{a\}, q_0, \Delta, F)$  be an NBA with  $Q = \{q_0, q_1\}$ ,  $F = \{q_1\}$ , and  $\Delta = \{(q_0, a, q_0), (q_0, a, q_1)\}$ . Then  $L(\mathcal{A}) = \emptyset$ .

The subset construction yields  $\mathcal{A}' = (\{\{q_0\}, \{q_0, q_1\}\}, \{a\}, \{q_0\}, \Delta, \{P \subseteq Q \mid P \cap F \neq \emptyset\})$  with  $\Delta = \{(\{q_0\}, a, \{q_0, q_1\}), (\{q_0, q_1\}, a, \{q_0, q_1\})\}$ . Therefore, the word  $a^\omega$  has an accepting run  $\{q_0\}\{q_0, q_1\}^\omega$ .  $\square$

**Theorem 1.6.** *Let  $\mathcal{A}$  be a Rabin automaton and let  $\rho_1, \rho_2, \rho$  be runs of  $\mathcal{A}$ . If  $\text{Inf}(\rho_1) \cup \text{Inf}(\rho_2) = \text{Inf}(\rho)$  and  $\rho_1$  and  $\rho_2$  are both non-accepting, then  $\rho$  is also non-accepting.*

*Proof.* Let  $\Omega = \{(E_i, F_i) \mid 1 \leq i \leq m\}$ . Let  $I_1 = \text{Inf}(\rho_1)$ ,  $I_2 = \text{Inf}(\rho_2)$ , and  $I = \text{Inf}(\rho)$ . Assume  $\rho$  is accepting, so there is an  $1 \leq i \leq m$  s.t.  $I \cap E_i = \emptyset$  and  $I \cap F_i \neq \emptyset$ . That means  $I \cap E_i = (I_1 \cup I_2) \cap E_i = \emptyset$ , so  $I_1 \cap E_i = I_2 \cap E_i = \emptyset$ . Since  $\rho_1$  and  $\rho_2$  are non-accepting, that means  $I_1 \cap F_i = I_2 \cap F_i = \emptyset$  and therefore  $I \cap F_i = \emptyset$ , which is a contradiction.  $\square$

**Theorem 1.7.** *For every  $n$ , there is  $L_n \subseteq \Sigma^\omega$  s.t. there is an NBA that recognizes  $L_n$  with  $n + 2$  states, but every det. Rabin automaton that recognizes  $L_n$  has at least  $n!$  states.*

*Proof.* We define the NBA  $\mathcal{A}_n = (Q, \Sigma_n, q_0, \Delta, F)$  with

- $\Sigma_n = \{\#, 1, \dots, n\}$
- $Q = \{q_0, q_f, q_1, \dots, q_n\}$
- $F = \{q_f\}$
- $\Delta$ :
  - For all  $1 \leq i \leq n$ , for all  $a \in \Sigma_n$ :  $q_i \xrightarrow{a} q_i$  and  $q_0 \xrightarrow{a} q_i$
  - For all  $1 \leq i \leq n$ :  $q_i \xrightarrow{i} q_f$  and  $q_f \xrightarrow{i} q_i$

Then  $\alpha \in L(\mathcal{A}_n)$  iff there are  $a_1, \dots, a_k \in \{1, \dots, n\}$  such that the words  $a_1 a_2, a_2 a_3, \dots, a_k a_1$  occur infinitely often in  $\alpha$ .

Let  $\mathcal{A}' = (Q', \Sigma_n, q'_0, \delta, \Omega)$  be a DRA for  $L(\mathcal{A}_n)$ . We want to show that  $\mathcal{B}$  has at least  $n!$  states. A permutation word is a word  $(i_1 \dots i_n \#)^\omega$  with  $\{i_1, \dots, i_n\} = \{1, \dots, n\}$ ; let PW be the set of permutation words. Let  $\alpha, \beta \in \text{PM}$  with  $\alpha \neq \beta$  and let  $\rho_\alpha, \rho_\beta$  the respective runs of  $\mathcal{B}$ . We claim that  $\text{Inf}(\rho_\alpha) \cap \text{Inf}(\rho_\beta) = \emptyset$ . If that is true, then  $|Q'| \geq |\text{PM}| = n!$ .

**Claim** :  $\text{Inf}(\rho_\alpha) \cap \text{Inf}(\rho_\beta) = \emptyset$

Let  $\alpha = (\bar{i}\#)^\omega$  and  $\beta = (\bar{j}\#)^\omega$  with  $\bar{i} = i_1 \dots i_n$  and  $\bar{j} = j_1 \dots j_n$ . Assume there is a  $q \in \text{Inf}(\rho_\alpha) \cap \text{Inf}(\rho_\beta)$ . We extract the following segments from the two runs:

- $\rho_1$  from  $\rho_\alpha$  with  $\rho_1 : q_0 \xrightarrow{w} q$  for some  $w \in \Sigma_n^*$ .
- $\rho_2$  from  $\rho_\alpha$  with  $\rho_2 : q \xrightarrow{w} q$  for some  $w \in \Sigma_n^* \bar{i} \Sigma_n^*$ .
- $\rho_3$  from  $\rho_\beta$  with  $\rho_3 : q \xrightarrow{w} q$  for some  $w \in \Sigma_n^* \bar{j} \Sigma_n^*$ .
- $\pi := \rho_1(\rho_2 \rho_3)^\omega$

Then  $\pi$  is a run of  $\mathcal{A}'$  on a word  $\gamma$  with  $\text{Inf}(\pi) = \text{Inf}(\rho_\alpha) \cup \text{Inf}(\rho_\beta)$ . Since  $\bar{i} \neq \bar{j}$ , there is a minimal  $k$  with  $i_k \neq j_k$ . By this choice, there must also be  $l, l'$  such that  $i_k = j_l$  and  $j_k = i_{l'}$ . Therefore, the following pairs all occur infinitely often in  $\gamma$ :

$$i_k i_{k+1}, i_{k+1} i_{k+2}, \dots, i_{l'-1} \underset{=j_k}{i_{l'}}, j_k j_{k+1}, \dots, j_{l-1} \underset{=i_k}{j_l}$$

As shown before, that means  $\gamma \in L(\mathcal{A}_n)$ , so  $\pi$  is an accepting run. This contradicts the Union Lemma (theorem 1.6).  $\square$

**Theorem 1.8.** *Given an ABA  $\mathcal{A}$ , the dual  $\tilde{\mathcal{A}}$  is an alternating co-Büchi automaton which accepts  $L(\mathcal{A})^c$ , with  $\tilde{F} = Q \setminus F$  and  $\tilde{\delta}$  exchanging true/false and  $\wedge/\vee$ .*

*Proof.* We claim that  $L(\mathcal{A})^c = L(\tilde{\mathcal{A}})$ .

$\subseteq$  Let  $\alpha \notin L(\mathcal{A})$ , so for every run tree  $t$  of  $\mathcal{A}$  on  $\alpha$ , there is a path  $\pi_t$  which is rejecting. One can show that the combination of all these paths is an accepting run of  $\tilde{\mathcal{A}}$ .

$\supseteq$  Let  $\alpha \in L(\mathcal{A})$ , so there is an accepting run tree  $t$ . Let  $\tilde{t}$  be a run tree of  $\tilde{\mathcal{A}}$  on  $\alpha$ . One can show (by induction on the path length) that there is a path in  $t$  that is also a path in  $\tilde{t}$ . Since that path is accepting in  $t$ , it must be rejecting in  $\tilde{t}$ .  $\square$

## 1.1 Minimization

**Theorem 1.9.** *There is a DBA-recog. language which does not have a unique minimal DBA. DBAs minimized with the DFA minimization algorithm can be arbitrarily bad compared to a minimal DBA.*

*Proof.* The language  $(a^*b)^\omega$  has two non-isomorphic DBAs.

For every  $n > 0$ , consider  $L_n = \{a^n\}$ . The minimal NFA for  $L_n$  has  $n + 1$  states but  $\lim(L_n) = \{a^\omega\}$  can be recognized by a DBA with a single state.  $\square$

**Theorem 1.10.** *Let  $U \subseteq \Sigma^\omega$  be regular and  $\sim_U$  be the Myhill-Nerode equivalence relation. Every DBA for  $U$  has at least  $\text{index}(\sim_U)$  many states.*

*Proof.* Assume  $\mathcal{A} = (Q, \Sigma, q_0, \delta, F)$  is a DBA for  $U$  with  $|Q| < \text{index}(\sim_U)$ . That means there are  $u, v \in \Sigma^*$  with  $u \not\sim_U v$  but  $\delta^*(q_0, u) = \delta^*(q_0, v)$ . By definition of the automaton, that means  $u \sim_U v$ , which is a contradiction.  $\square$

**Theorem 1.11.** *For every  $n$ , there is a  $U_n \subseteq \Sigma^\omega$  such that  $\text{index}(\sim_{U_n}) = 1$  but every DBA for  $U_n$  has at least  $n$  states.*

*Proof.* Let  $U_n = \{\alpha \mid a^n b \text{ appears infinitely often as a substring in } \alpha\}$ . The language is prefix independent, so  $\text{index}(\sim_{U_n}) = 1$ . However, a DBA for  $U_n$  clearly requires  $n + 1$  states.  $\square$

**Theorem 1.12.** *The problem  $\text{DBA}_{\text{MIN}} = \{(\mathcal{A}, k) \mid \mathcal{A} \text{ DBA}, k \in \mathbb{N}, \text{ There is a } k\text{-state DBA for } L(\mathcal{A})\}$  is NP-complete.*

**Definition 1.** *For  $U \subseteq \Sigma^\omega$ , we define the canonical automaton  $\mathcal{A}_U = (Q_U, \Sigma, q_0^U, \delta_U, F_U)$  with*

- $Q_U = \{[u]_{\sim_U} \mid u \in \Sigma^*\}$
- $q_0^U = [\varepsilon]_{\sim_U}$
- $\delta_U([u]_{\sim_U}, a) = [ua]_{\sim_U}$
- $F_U = \{[u]_{\sim_U} \mid \exists v \in \Sigma^+ : u \sim_U uv \text{ and } uv^\omega \in U\}$

**Theorem 1.13.** *Let  $U$  be WDBA-recognizable. Then  $\mathcal{A}$  is a WDBA and  $L(\mathcal{A}_U) = U$ .*

*Proof.* We show the statement in two steps.

**Claim** :  $\mathcal{A}_U$  is a WDBA.

Let  $[u]_{\sim_U}, [v]_{\sim_U} \in Q_U$  be two states in the same SCC and  $[u]_{\sim_U} \in F_U$ . We need to show that  $[v]_{\sim_U} \in F_U$  as well. Since the two states are in the same SCC, let  $\mathcal{A}_U : [u]_{\sim_U} \xrightarrow{y} [v]_{\sim_U} \xrightarrow{z} [u]_{\sim_U}$ . We have  $u(yz)^\omega \in U$ .

Hence,  $uy(zy)^\omega \in U$ . By definition we know  $[uy]_{\sim_U} = [u']_{\sim_U}$ , so  $u'(zy)^\omega \in U$  which means that  $[u']_{\sim_U} \in F_U$ .

**Claim** :  $L(\mathcal{A}_U) = U$ .

Let  $uv^\omega$  be an ultimately periodic word. By the pigeon hole principle, there are  $m, n > 0$  such that  $uv^m \sim_U uv^m v^n$ .

$$\begin{aligned} uv^\omega &\in U \\ \Leftrightarrow uv^m(v^n)^\omega &\in U \\ \Leftrightarrow [uv^m]_{\sim_U} &\in F_U \\ uv^m \sim_U uv^m v^n &\Leftrightarrow uv^m(v^n)^\omega \in L(\mathcal{A}_U) \\ \Leftrightarrow uv^\omega &\in L(\mathcal{A}_U) \end{aligned}$$

Now consider  $X = (U \cup L(\mathcal{A}_U)) \setminus (U \cap L(\mathcal{A}_U))$ . If the two languages are equal, then  $X$  must be empty. As we have shown above,  $U$  and  $L(\mathcal{A}_U)$  contain the same ultimately periodic words, so  $X$  does not contain any. It is also constructed by Boolean operations on regular languages, so  $X$  must be regular. That means that  $X = \emptyset$ .  $\square$

**Definition 2.** Let  $\mathcal{A} = (Q, \Sigma, q_0, \Delta, F)$  be an NBA. A **looping state** is a state in  $Q$  from which there is a non-empty path that ends in that same state.

We define the **acceptance height**  $ah : Q \rightarrow \mathbb{N}$  as follows: Let  $q \in Q$ . If all looping states that are reachable from  $q$  are accepting, then  $ah(q) := 0$ . Otherwise, let  $n$  be the maximal acceptance height of a state that is reachable from  $q$  but not in the same SCC. If  $q$  is non-looping, set  $ah(q) := n$ . Otherwise,

$$ah(q) := \begin{cases} 2 \cdot \lfloor \frac{n-1}{2} \rfloor + 2 & \text{if } q \in F \\ 2 \cdot \lfloor \frac{n}{2} \rfloor + 1 & \text{if } q \notin F \end{cases}$$

$\mathcal{A}$  is in **normal form** if  $F = \{q \in Q \mid ah(q) \text{ is even}\}$ .

**Theorem 1.14.** Let  $\mathcal{A}$  be a weak DBA. One can compute an equivalent weak DBA in normal form in linear time.

*Proof.* SCCs can be computed in linear time. Given the SCCs, the inductive definition of  $ah$  can be computed in linear time.  $\square$

**Theorem 1.15.** Let  $\mathcal{A}$  be a weak DBA in normal form. Minimizing  $\mathcal{A}$  as a DFA also results in a minimal weak DBA.

## 1.2 Simulation Game

**Definition 3.** Let  $\mathcal{A} = (Q, \Sigma, q_0, \Delta, F)$  be an NBA. We define the delayed simulation game  $\mathcal{G}_{\mathcal{A}}(G_{\mathcal{A}}, \text{Win})$  as follows

- $G_{\mathcal{A}} = (V_0, V_1, E, c)$
- $V_0 = \Sigma \times Q \times Q$
- $V_1 = Q \times Q$
- Player 0 moves from  $(a, p, q)$  to  $(p, p')$  with  $(q, a, p') \in \Delta$
- Player 1 moves from  $(q, q')$  to  $(a, p, q')$  with  $(q, a, p) \in \Delta$
- $c : V \rightarrow \{-1, 0, 1\}$  with  $c(v) = \begin{cases} -1 & \text{if } v \in F \times (Q \setminus F) \\ 1 & \text{if } v \in Q \times F \\ 0 & \text{otherwise} \end{cases}$
- $\alpha \in \text{Win}$  iff after every -1 in  $\alpha$ , there is a 1 later on.

Write  $q \preceq_{de} q'$  if player 0 has a winning strategy from  $(q, q')$ .

Idea: Player 1 chooses symbols in  $\Sigma$  and transitions on the second state. Player 0 has to answer with transition on the first state which lead to a run of the same acceptance.

**Theorem 1.16.** If  $q \preceq_{de} q'$  and  $q' \preceq_{de} q$ , then  $q$  and  $q'$  can be merged in  $\mathcal{A}$  without changing the language of the automaton.

**Theorem 1.17.** The delayed simulation game can be reduced to a Büchi game in linear time.

## 2 Finite Trees

**Theorem 2.1** (Pumping Principle). *Let  $T \subseteq T_\Sigma$  be a regular ranked tree language. There is a  $n \in \mathbb{N}$  such that for all trees  $t \in T$ , all  $m > n$ , and all paths  $\pi_1 \dots \pi_m$ , there are  $1 \leq i < j \leq m$  such that for all  $k \in \mathbb{N}$ :*

$$t[\circ/u] \cdot (t[\circ/v]|_u)^k \cdot t|_v \in T$$

where  $u = \pi_1 \dots \pi_i$  and  $v = \pi_1 \dots \pi_j$ .

**Definition 4.** Let  $T \subseteq T_\Sigma$ . The **Myhill-Nerode equivalence** is  $\sim_T \subseteq T_\Sigma \times T_\Sigma$  with

$$t_1 \sim_T t_2 \Leftrightarrow \forall s \in S_\Sigma : s \cdot t_1 \in T \Leftrightarrow s \cdot t_2 \in T$$

The index of  $T$  is  $\text{Index}(\sim_T) := |T / \sim_T|$ .

**Definition 5.** Let  $T \subseteq T_\Sigma$ . We define the canonical DTA  $\mathcal{A}_T = (Q_T, \Sigma, \delta_T, F_T)$  as

- $Q_T = \{[t]_{\sim_T} \mid t \in T_\Sigma\}$ .
- For all  $a \in \Sigma_i$ :  $\delta_T([t_1]_{\sim_T}, \dots, [t_i]_{\sim_T}, a) = [a(t_1, \dots, t_i)]_{\sim_T}$ .
- $F_T = \{[t]_{\sim_T} \mid t \in T\}$ .

**Theorem 2.2.** Let  $T \subseteq T_\Sigma$ .  $T$  is regular iff  $\text{Index}(\sim_T)$  is finite. If  $T$  is regular,  $\mathcal{A}_T$  is the minimal DTA.

*Proof.* via induction on  $t$ , prove  $\delta_T^*(t) = [t]$  □

**Theorem 2.3.** The emptiness problem for NTAs can be reduced to HORN-SAT in linear time.

*Proof.* Let  $\mathcal{A} = (Q, \Sigma, \Delta, F)$  be an NTA. For every  $\tau = (q_1, \dots, q_i, a, p) \in \Delta$ , let  $\psi_\tau = (X_{q_1} \wedge \dots \wedge X_{q_i} \rightarrow X_q)$ . Then we define  $\varphi = \bigwedge_{\tau \in \Delta} \psi_\tau \wedge \bigwedge_{q \in F} X_q \rightarrow 0$ .  $\varphi$  is satisfiable iff  $L(\mathcal{A}) \neq \emptyset$ . □

### 2.1 BTTs

**Theorem 2.4.** The equivalence problem for BTTs is undecidable.

*Proof.* Follows from the equivalence problem of rational word transducer. □

**Theorem 2.5.** The emptiness problem for BTTs is decidable in polynomial time.

*Proof.* One can construct in polynomial time a  $\uparrow$ NTA that recognizes the domain of a given BTT. The emptiness problem of BTTs then is equivalent to the emptiness problem of  $\uparrow$ NTAs. □

**Theorem 2.6.** The type-checking problem (given regular  $T, T'$ , is  $\mathcal{A}(T) \subseteq T'?$ ) is decidable.

*Proof.*  $\mathcal{A}(T) \subseteq T'$  iff  $\mathcal{A}^{-1}((T')^c) \cap T = \emptyset$ . If  $T'$  is regular then so is  $\mathcal{A}^{-1}((T')^c) \cap T$  and this can be decided. □

**Theorem 2.7.** If  $T$  is regular, then  $\mathcal{A}^{-1}(T)$  is regular.  
If  $\mathcal{A}$  is linear, then  $\mathcal{A}(T_\Sigma)$  is regular.

**Theorem 2.8.** *There are BTT-definable relations  $R_1, R_2$  such that  $R_1 \circ R_2$  is not BTT-definable.*

*Proof.* Let  $\Sigma = \{f, g, h, c\}$  and for both  $i \in \{1, 2\}$ :  $\mathcal{A}_i = (\{q, q_f\}, \Sigma, \Sigma, \Delta_i, \{q_f\})$  where

•  $\Delta_1$ :

- $c \rightarrow q(c)$
- $g(q(x_1)) \rightarrow q(g(x_1))$
- $q(x_1) \rightarrow q_f(f(x_1))$

•  $\Delta_2$ :

- $c \rightarrow q(c)$
- $g(q(x_1)) \rightarrow q(g(x_1))$
- $g(q(x_1)) \rightarrow q(h(x_1))$
- $f(q(x_1), q(x_2)) \rightarrow q_f(f(x_1, x_2))$

$\mathcal{A}_1$  converts a tree  $t \in T_{\{c, g\}}$  to  $f(t, t)$ .  $\mathcal{A}_2$  replaces an arbitrary number of  $g$ s by  $h$ s.  $R_1 \circ R_2$  defines the set of trees  $f(t_1, t_2)$  where  $t_1$  and  $t_2$  are of equal height.  $\square$

**Theorem 2.9.** *If  $\mathcal{A}_1$  is linear or  $\mathcal{A}_2$  is deterministic Then  $R(\mathcal{A}_1) \circ R(\mathcal{A}_2)$  is BTT-definable.*

### 3 Infinite Trees

**Theorem 3.1** (BTA Pumping). *For  $t \in T_\Sigma, x \in \{0, 1\}^*, y \in \{0, 1\}^+$ , let*

$$t_{[x, y]}^* : \{0, 1\}^* \rightarrow \Sigma, z \mapsto \begin{cases} t(z) & \text{if } xy \not\sqsubseteq z \\ xz' & \text{if } \exists n > 0 : z = xy^n z' \text{ with } y \not\sqsubseteq z' \end{cases}.$$

*Let  $\mathcal{A}$  be a BTA,  $t \in T(\mathcal{A})$ ,  $\rho$  an accepting run of  $\mathcal{A}$  on  $t$ , and  $x, y, y' \in \{0, 1\}^*$  s.t.  $\rho(x) = \rho(xy)$ ,  $y' \sqsubset y$ , and  $\rho(xy') \in F$ . Then  $t_{[x, y]}^* \in T(\mathcal{A})$ .*

*Proof.*  $\rho_{[x, y]}^*$  is an accepting run of  $\mathcal{A}$  on  $t_{[x, y]}^*$ .  $\square$

**Theorem 3.2.** *Every non-empty regular tree language contains a regular tree.*

*Proof.* Let  $\mathcal{A}$  be a PTA for  $T = T(\mathcal{A}) \neq \emptyset$  and let  $\mathcal{G}_{\mathcal{A}}$  be the emptiness game for  $\mathcal{A}$ . Since  $T$  is not empty, player Automaton has a positional winning strategy  $\sigma : Q \rightarrow \Sigma$ . For  $\sigma(q) = (q, a, q_0, q_1)$ , we define  $\delta_\sigma(q, 0) = q_0$ ,  $\delta_\sigma(q, 1) = q_1$ , and  $f_\sigma(q) = a$ . Then  $t \in T$  where  $t$  is the regular tree defined by  $\mathcal{B} = (Q, \{0, 1\}, q_0, \delta_\sigma, f_\sigma)$ .  $\square$

**Theorem 3.3** (Rabin's Tree Theorem). *The MSO theory of  $\underline{T_2}$  is decidable for formulas  $\varphi(X_1, \dots, X_n)$  and a model  $X_1, \dots, X_n \subseteq \{0, 1\}^*$  is computable.*

*Proof.* Transform  $\varphi$  into an equivalent PTA. A model can be found by solving the emptiness game.  $\square$
